## Tests of Distinguishability and Nonindependence

November 27, 2015

## 1. Text

CAUTION: If you do decide to use information contained here in a paper, please make sure that you acknowledge that you have used this program. Also should you decide to use the exact text included here, you will need to put quotes around that material to avoid plagiarism. Although great effort has been undertaken to ensure the accuracy of results, no complete guarantee can be about their accuracy. It is your responsibility to check the results and text for accuracy. If you do find an error, please report it to David A. Kenny.

## Tests of Distinguishability

The focus is to determine whether Gender makes a statistical difference in the data, and if it does, what is that difference. That is, are there differences between Husbands and Wives for the mixed variables Other Positivity, Self Positivity, Similar Hobbies, and Satisfaction, the between-dyads variable Years Married, and the within-dyads variable Tension Difference? There are 148 dyads in the sample and no missing data. The mixed variables in the dataset for Husbands are OtherPos_H, SelfPos_H, SimHob_H, and Satisfaction_H, the variables for Wives are OtherPos_W, SelfPos_W, SimHob_W, and Satisfaction_W, and their names for the text are Other Positivity, Self Positivity, Similar Hobbies, and Satisfaction. The between-dyads variable in the dataset is yearsmar and its name for the text is Years Married. The within-dyads variable in the dataset for Husbands is Tdiff_H and for Wives is Tdiff_W,and its name in the text is Tension Difference. The analyses employ the method of structural equation modeling using the computer program of lavaan. The means and standard deviations of each variable for both Husbands and Wives are presented in Table 1. Note that the estimates are maximum likelihood estimates and so the standard deviations are a bit larger than conventional estimates.

There are three ways in which Gender can make a difference. They are differences between the variables in their means, in their variances, and differences between correlations between the two variables. To test if correlations differ, the variances must be set equal for the two members. Note too that the correlations may differ, but cross-variable effects (e.g., actor and partner effects in the Actor-Partner Interdependence Model) might not differ. For a within-dyads variable the correlations whould be equal across members but their signs would be different. For instance, the means and variances of Other Positivity might differ for Husbands and Wives. Also for the within-dyads variable of Tension Difference the means for both Husbands and Wives would not both equal 2.000. For correlation, an example is that the correlations between Other Positivity and Self Positivity might be different for Husbands and Wives. Another example is that the correlations between Other Positivity and Years Married or with Tension Difference might be different for Husbands and Wives.

Tables 2 and 3 provide the measures of fit for five models which allow for different types of distinguishability and also there is a table of the tests of hypotheses. (To learn about measures of fit go to davidakenny.net/cm/fit.htm -- reverse the slashes. The RMSEA must be less than 0.08 to be considered a good-fitting model.) To begin, the test that the means for each variable are equal (Model I versus Model II) is statistically significant (chi-square (5) $=46.58, \mathrm{p}<.001$ ). Thus, there is evidence that the means are unequal. Next,
the test of whether the correlations between pairs of variables are equal (Model I versus Model III) is not statistically significant (chi-square(20) = 18.52, p = .553). Thus, the data are consistent with the hypothesis that the correlations are equal, given that the variances are equal. Lastly, the test that the variances are equal (Model IV versus Model V) is statistically significant (chi-square (4) = 10.10, $\mathrm{p}=.039$ ). Thus, there is evidence that the variances are unequal. In terms of fit indices, the Means Unequal Model or Model II appears to be the best model as it has the lowest value of the RMSEA and the SABIC.

The model of complete indistinguishability is called the I-Sat model by Olsen and Kenny (2006) and that model has a chi square of 75.636 with 29 degrees of freedom. The null model for the indistinguishable case (the model that fixes all correlations to zero, but frees the means and variances and sets them equal across the two members) is 299.528 with 44 degrees of freedom.

## Test of Nonindependence

Additionally, the question is whether the scores of the Husbands and Wives are correlated, i.e., nonindependent. There are 16 correlations between the scores of Husbands and Wives, and the null hypothesis is that these correlations are all zero. The effects due to the between-dyads variables have been removed in tests of nonindependence. Table 4 contains the results from these tests. (Note that SABIC(Sat) refers to the SABIC for the saturated model. Also for the RMSEA 0.08 is used as the cutoff for a good fitting model. Treating dyad members as distinguishable, there is good evidence that there is nonindependence or correlation between the scores of Husbands and Wives. Alternatively, if we treat dyad members as indistinguishable, there is good evidence that there is nonindependence or correlation between the scores of Husbands and Wives.

## 2. Tables

Table 1: Descriptive Statistics for Husbands and Wives

| Person | Husbands |  | Wives |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
|  | Mean | SD | Mean | SD |
| Other Positivity | 4.281 | 0.472 | 4.246 | 0.521 |
| Self Positivity | 4.082 | 0.389 | 4.291 | 0.408 |
| Similar Hobbies | -0.034 | 0.682 | 0.189 | 0.585 |
| Satisfaction | 3.618 | 0.460 | 3.591 | 0.528 |
| Years Married | -0.000 | 7.694 | -0.000 | 7.694 |
| Tension Difference | 1.821 | 0.782 | 2.179 | 0.782 |

Table 2: Tests of Different Types of Distinguishability

| Model | Equal | Means Equal | Variances | Equal | Correlations | chi | square | df | p | RMSEA |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | SABIC

Table 3: Tests of Hypotheses of Different Types of Distinguishability

|  | Test chi square | df | p | value |
| ---: | ---: | ---: | ---: | ---: |
| Means | I versus II | 46.583 | 5 | $<.001$ |
| Correlations I versus III | 18.521 | 20 | .553 |  |
| Variances | IV versus V | 10.096 | 4 | .039 |

Table 4: Tests of Nonindependence across Husbands and Wives

|  | chi square df | p value | RMSEA | SABIC | SABIC(Sat) |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Distinguishable | 115.362 | 16 | $<.001$ | 0.205 | 185.000 | 98.959 |
| Indistinguishable | 102.966 | 10 | $<.001$ | 0.251 | 130.454 | 45.815 |
